## 1 PROJECT BACKGROUND

### 1.1 INTRODUCTION

This report presents the results of a wind tunnel study of pedestrian wind conditions around the Michael Fowler Centre Carpark development, which is proposed for a site between Jervois Quay and Wakefield Street in central Wellington. The proposal for this approximately triangular site involves the development of an eight-storey building combining office and retail space.

The objective of the wind tunnel study is to quantify the extent and magnitude of any significant effects of the proposed development on pedestrian level wind conditions in the surrounding public areas. This investigation is required (1) to meet the reporting requirements of the Wellington City District Plan relating to the wind effects of new buildings and (2) as part of the resource consent process.

### 1.2 WELLINGTON DISTRICT PLAN – WIND EFFECTS

The Wellington City District Plan contains objectives, policies and standards relating to the potential effects of new buildings on pedestrian wind conditions in various parts of the city, particularly in the Central Area. The intent is to ensure that buildings are designed to avoid, remedy or mitigate potential adverse effects and to improve the wind environment where reasonably practical. Performance criteria have been set in the District Plan with three main goals in mind. The first of these is a Safety Criteria, which is specified in terms of a maximum gust speed of 20m/s. The second criteria use a "frequency of occurrence" approach to define an acceptable level of comfort and the third criteria use the change in "frequency of occurrence" to limit the overall deterioration in wind conditions that can occur with a proposed development. Sections of the District Plan specifically relating to wind effects are reproduced in Appendix B for ready reference.

## 2 SITE, AREA AND PROPOSED DEVELOPMENT

### 2.1 DEVELOPMENT SITE

The Michael Fowler Centre Carpark development site is an approximately flat triangular shaped area located between Jervois Quay and Wakefield Street, to the east of the Michael Fowler Centre, in central Wellington. It is currently occupied by a low-rise (9-10m) pitched-roof building tenanted by the Royal New Zealand Ballet, with the remainder of the site being carparking and landscaped open space.

### 2.2 SURROUNDING AREA

Buildings in the surrounding area range from older low-rise buildings that are one or two storeys high through to medium-rise and high-rise blocks of ten storeys or more. This area of Wellington has seen limited redevelopment in recent years. The most significant new building nearby is the 1 Market Lane development, which was completed in 2015. Work is also currently being completed on the refurbishment of the Wellington City Council buildings surrounding Civic Square, further to the west of the site of interest.

### 2.3 PROPOSED DEVELOPMENT

The development proposal involves the construction of an eight-storey building around 37m tall. It can loosely be described as having a triangular planform at ground level, with the higher floors projecting out firstly at the southwest corner and then the northwest corner, before the building facades step back from both the eastern and western ends. This creates two undercrofts in these areas. The upper levels of the western end of the building also have a series of evenly spaced vertical projecting fins across this curved façade. There is a conventional canopy along the Wakefield Street frontage, except across the section of undercroft at the southwest corner of the building.

Figure 1 shows views of the wind tunnel model of the development and the immediate surroundings. These show the articulation of the different building elements, both horizontally and vertically. Figure 2 shows an aerial photo of the area around the development site. Superimposed on this is a plan of the development site. Also included on this figure are the direction sectors for the prevailing winds over Wellington City and the locations of the wind speed measurements.

## 3 WIND TUNNEL TEST PROCEDURES

### 3.1 GENERAL

Testing was performed in the WSP Research and Innovation Centre re-circulating wind tunnel, using a 1:264 scale model of the proposed development and the surrounding area of Wellington. The model of the development was positioned approximately at the centre of the wind tunnel turntable, with the surrounding area modelled to a full-scale radius of approximately 300-400m. The wind tunnel boundary layer was set up to reproduce conditions for Terrain Category 3, as defined in Appendix D, for all the wind directions.

The following two methods of testing were employed.

### 3.2 FLOW VISUALISATION

Flow visualisation provides a means of quickly identifying the areas of highest relative wind speed on the surface of the model. The test method involves sprinkling a thin layer of small bran flakes on the model surface and then running the wind tunnel at increasing speeds. A camera mounted directly above the model is used to record the erosion patterns as the test proceeds. The areas cleared first are assumed to be the windiest. Details of the test method are given in Appendix E. Flow visualisation tests were carried out for the four wind directions, 170°, 210°, 320° and 360°, which are representative of the prevailing wind directions for Wellington City (refer Appendix C). These were carried out for the existing situation and the proposed development.

### 3.3 WIND SPEED MEASUREMENTS

Wind speed measurements made with a hot-film anemometer involve measuring the ratio of the wind speeds at a location on the model (at a scale height of 2 metres) to a reference wind speed (at a scale height of 150 metres). Using these measurements and relating them to full-scale meteorological wind data, it is possible to estimate the wind conditions that will be experienced at a location and therefore classify the wind performance of the area by measuring speeds at many locations (refer Appendix A). The wind speed measurements were made using a hot-film anemometer for the eight wind directions 150°, 170°, 190°, 210°, 320°, 340°, 360° and 020°. These measurements were carried out for the existing situation and the proposed development.

The measured wind speed data is processed in two different ways:

1 The mean wind speed and the corresponding standard deviation in the wind speed are combined to provide a "calculated gust speed".

The calculated gust speed,  $V_c$ , is defined as:  $V_c = V_{mean} + 3.7 V_{rms}$ 

where  $V_{mean}$  is the maximum annual hourly mean wind speed, and  $V_{rms}$  is the standard deviation corresponding to this mean speed. The calculated gust speeds are compatible with the Safety Criteria for wind speeds specified in the Wellington City District Plan (refer Appendix B).

2 The mean wind speeds for each location for each wind direction are divided by the directional mean reference wind speed to provide a mean velocity ratio. These are then combined with the

Wellington City wind climate data listed in Appendix C to calculate the number of days for which mean wind speeds of 2.5m/s and 3.5m/s are equalled or exceeded in a year.

## 4 FLOW VISUALISATION TESTS

### 4.1 BACKGROUND

Photographic records of each flow visualisation test have been processed to give contour images that show the relative degree of windiness in the area around the development. These images are shown in Figures 3 to 6. The images in each figure (as described in Appendix E) show the wind patterns for the existing situation and then those with the proposed development. All the photographs are mounted so that the wind flow is from the right side of the page. The development site is located approximately in the centre of the photographs.

### 4.2 NORTHERLY WINDS

The main observations from the flow visualisation studies for northerly winds are:

- (a) Much of the area of Wellington around the development site is currently well sheltered from northwesterly winds from 320° by the upstream buildings. The exception to this is the space between the 1 Market Lane building on the north side of Jervois Quay and the buildings on the south side of Wakefield Street, primarily the Amora Hotel. As the wind direction shifts to the north (360°), the whole area becomes more exposed, with strong horizontal wind flows across the relatively open waterfront area and also along the south side of Wakefield Street.
- (b) For both wind directions of 320° and 360° the erosion images show that the proposed development deflects additional wind flows down and along the curved western façade and the Jervois Quay façade into the adjacent areas around the western end of the new building. In contrast, the erosion images for both wind directions also suggest that the proposed development affords areas downwind, primarily in Wakefield Street, with increased shelter.

### 4.3 SOUTHERLY WINDS

The main observations from the flow visualisation studies for southerly winds are:

- (a) In southerly winds there are distinct differences in the flow patterns with wind direction. For wind from 170° strong horizontal wind flows are evident along Taranaki Street and Wakefield Street and these stream along Jervois Quay towards the north. However, the south side of Wakefield Street adjacent to the site remains reasonably well sheltered by the compact block of upstream buildings. As the wind direction shifts to the southwest (210°) the shelter afforded by these buildings becomes more pronounced. For this wind direction the local wind environment is dominated by wind flows deflected down and along the windward face of the 1 Market Lane building, across Jervois Quay from the site.
- (b) The contour images for both southerly wind directions show that the proposed development does deflect some wind flow down and along its windward south side into the adjacent part of Wakefield Street. However, these effects generally appear to be moderate. The erosion patterns indicate that the new building affords some areas downstream with increased shelter.

## 5 WIND SPEED MEASUREMENTS

### 5.1 RESULTS

Wind speeds were measured for the existing situation and the proposed development for the eight wind directions described in Section 3. The maximum calculated gust wind speeds at each location out of the eight wind directions are listed in Table 1. These speeds can be compared with the District Plan Safety Criteria wind speed of 20m/s. A change of 1 m/s in the wind speed is not considered significant within the limitations of the test method. Figure 7 shows those locations where the proposed development has either (1) increased or decreased the gust speed by 2m/s or more, or (2) increased the gust speed above the 20m/s Safety Criteria. The calculated gust speed for individual directions are listed in Appendix F.

## 6 FREQUENCY OF OCCURRENCE

### 6.1 RESULTS

The wind speeds listed in Section 5, and in Appendix F, can also be described in terms of the number of days per year the District Plan Cumulative Effect mean wind speeds of 2.5m/s) and 3.5m/s will be equalled or exceeded. This does not change the underlying data, but simply changes the variable from wind speed to days per year. Tables 2 and 3 list the total days per year that 2.5m/s and 3.5m/s are equalled or exceeded respectively, for the existing situation and the proposed development. An increase of 20 days/year is the maximum change that is acceptable according to the Wind Standard. Note that, in this context, a day is defined as a cumulative duration of 24 hours, which may be spread over several calendar days and different wind directions.

Table 2: Notes: Days per year Cumulative Effect Criteria (2.5m/s) Are Equalled or Exceeded. Exg = existing situation, New = proposed development, - = not measured.

Figure 8 shows the differences in the time for which the Cumulative Effect Criteria threshold of 2.5m/s is exceeded between the existing situation and the proposed development. The diagram for the Cumulative Effect Criteria Threshold of 3.5m/s has not been reproduced as the locations of the changes and the general trends in the data are similar.

![](_page_20_Figure_0.jpeg)

Figure 8:

Changes in Number of Days Exceeding 2.5m/s Cumulative Effect Criteria.

## 7 DISCUSSION OF RESULTS

### 7.1 EXISTING LOCAL WIND ENVIRONMENT

Wind conditions in the area around the development site are largely determined by a combination of (1) the orientation of the streets to the prevailing wind directions, (2) the width of the streets, and (3) the exposure to direct wind flows that different buildings have because of their height or because of open ground upwind of them.

Existing wind conditions around the site range from low to high, with maximum gust speeds at around a half a dozen locations exceeding the 20m/s District Plan Safety Criteria.

### 7.2 HOT-FILM WIND SPEED MEASUREMENTS

Table 4 below summarises the calculated gust speed data from Table 1 and Appendix F. Included in this table are the numbers of locations where the 20m/s Safety Criteria gust speed threshold is exceeded.

#### Table 4:

#### Summary of Calculated Gust Speed Results.

Exg = existing situation, New = proposed development, - = Not Measured

	Configuration						
Parameter	Exg	New					
Maximum Gust Speed (m/s)1	23	24					
Minimum Gust Speed (m/s)1	10	9					
Number of locations where calculated gust speed $V_c$ > 20m/s	7	5					
Number of <b>increases</b> in gust speeds Vc of 2m/s or more (Exg – New)	8						
Number of locations where gust speeds Vc are <b>increased</b> over 20m/s	2	<u>-</u>					
Number of <b>reductions</b> in gust speeds Vc of 2m/s or more (Exg - New) 12							
Number of locations where gust speeds Vc over 20m/s are <b>reduced</b>	Z	ŀ					

1 - maximum or minimum from the eight wind directions measured

Tables 1 and 4, and Figures 7 show the following:

- The lowest gust speeds are about the same for the existing situation and the proposed development.
- The highest gust speeds are about the same for the existing situation and the proposed development.
- There are more reductions (12) in gust speeds of 2m/s or greater with the development than there are increases (8) of 2m/s or more.

- There are more locations where the development reduces an existing maximum gust speeds of greater than 20m/s that there are locations where it increases the maximum gust speed above 20m/s.
- Overall, the proposed development causes a relatively small change in the local gust wind speed environment, with the effects being primarily a redistribution of wind conditions.

### 7.3 FREQUENCY OF OCCURRENCE DATA

#### 7.3.1 CUMULATIVE EFFECT CRITERIA

Table 5 summarises the frequency of occurrence data for both the 2.5m/s and 3.5m/s Cumulative Effect Criteria. Included in this table are the numbers of locations where changes in the frequency of occurrence are greater than ±20days/year. An increase of 20 days/year is the maximum acceptable change allowed for by the Wind Standard at a specific location. The parameters described are intended to provide an overview of how the development is performing.

Parameter	speed =	2.5 m/s	speed = 3.5 m/s		
	Exg	New	Exg	New	
Maximum Days Exceeding the speed (at any location)	216	210	149	153	
Minimum Days Exceeding the speed (at any location)	0	1	0	0	
No of locations where speed <b>increases</b> (Exg to New) > 20 days	8 5				
No of locations where speed <b>decreases</b> (Exg to New) > 20 days	1	1	7		
Largest <b>increase</b> in days exceeding speed (Exg to New)	15	54	103		
Largest <b>decrease</b> in days exceeding speed (Exg to New)	-8	39	-55		

## Table 5:Summary of Frequency of Occurrence Data.Exg = existing situation, New = proposed development, - = Not Measured

Tables 2, 3 and 5 and Figure 8 show the following:

- The maximum number of days the speed is exceeded is about the same for the existing situation and the proposed development for the 2.5m/s threshold and for the 3.5m/s threshold.
- The minimum number of days the speed is exceeded is about the same for the existing situation and the proposed development.
- The number of locations where the proposed development increases the time that the mean speed equals or exceeds the Cumulative Effect thresholds of 2.5m/s and 3.5m/s is slightly lower than the number of locations where it reduces the time. For the most part the sizes of the increases and reductions are comparable.
- Overall, the proposed development represents mostly a redistribution of the amenity of the pedestrian wind speed environment in the surrounding area, with the area around

the western end of the new building getting generally worse and the area around the eastern end of the new building getting generally better.

### 7.4 OVERALL ASSESSMENT OF BUILDING DESIGN

New buildings, of the scale that is proposed, will often have a significant impact on wind conditions in the surrounding public areas, footpaths and pavements. In this case, while the wind tunnel data shows that the proposed development does cause significant changes in wind conditions, mostly due to redistribution of wind flows, the net overall effect is relatively small. Increases identified around the western end of the new building are more than offset by reductions around the eastern end of the new building. This relatively small overall change in the wind environment can be partially attributed to beneficial aspects of the building design, which include the building massing, with setbacks and stepped facades on the eastern and western ends of the building.

### 7.5 INVESTIGATION OF DESIGN CHANGES

Having identified two locations where the maximum gust speeds were increased above the 20m/s Safety Criteria, it was considered appropriate to investigate the effect of design configuration changes and potential wind mitigation options. Accordingly, a range of mitigation options were developed. These are listed below, and their locations and approximate dimensions are shown in Figure 9.

- (1) A 2m high porous screen on the edge of the ground level plinth (~east west).
- (2) A 2m high porous screen on the edge of the ground level plinth (~north south).
- (3) A 2m high porous screen adjacent to Jervois Quay, on the west side of the waterfront connection linking Jervois Quay and Wakefield St.
- (4) Additional mature evergreen trees and planting in the triangle adjacent to Jervois Quay, on the west side of the waterfront connection linking Jervois Quay and Wakefield St.
- (5) A 2m wide canopy along the edge of the lower part of the undercroft on the west side of the building.

![](_page_23_Figure_10.jpeg)

Figure 9: Wind mitigation options (as listed above, includes measurement locations).

Additional wind speed measurements were carried out for selected locations and wind directions for the options listed above. The results of these measurements are listed in Table 6.

#### Table 6:Effects of Mitigation Options - Maximum Calculated Gust Speeds, Vc (m/s).

Notes: E = with existing situation, N = with original design, 1 = Option 1, 2 = Option 2 = calculated gust speed > 20m/s Safety Criteria, - = not measured

	320°					340°						360°									
Location	Е	N	1	2	3	4	5	Е	N	1	2	3	4	5	Е	N	1	2	3	4	5
U	9	18	19	19	-	16	15	13	21	21	21	-	19	18	12	21	21	21	-	20	20
A1	8	17	-	-	-	16	-	10	19	-	-	-	16	-	10	12	-	-	-	-	-
C1	12	22	-	-	22	20	-	14	20	-	-	21	19	-	14	13	-	-	-	-	-

The results show that Option 4 (additional trees and planting) and Option 5 (undercroft canopy) had some beneficial effects in reducing gust speeds, including reducing speeds to 20m/s or below.

## 8 CONCLUSIONS

The following conclusions have been drawn from a wind tunnel study of pedestrian wind conditions around the proposed development for the Michael Fowler Centre carpark in central Wellington.

#### **Existing Wind Conditions**

1 Existing wind conditions around the development site range from low to high, with maximum gust speeds at a small number of locations exceeding the 20m/s District Plan Safety Criteria.

#### Gust Speeds - Safety Criteria

- 2 The gust speed data shows that, taken overall, the development causes a relatively small change in the local pedestrian wind environment. However, it does cause a significant redistribution of wind flows in the surrounding area, causing some speeds to increase and others to decrease. Most of the increases identified occurred around the western end of the new building, while most of the reductions occurred around the eastern end.
- **3** There are twelve locations where the gust speeds are reduced with the original development design, compared to eight locations where the gust speed is increased. At two of these locations the gust speeds are increased over the 20m/s District Plan Safety Criteria by the development, while at four locations existing gust speeds over 20m/s are reduced.

#### Frequency of Occurrence - Cumulative Effect Criteria

4 There are more locations where the development reduces the time that the mean speed equals or exceeds the District Plan Cumulative Effect thresholds of 2.5m/s and 3.5m/ by more than 20 days/year than where it increases the time by more than 20days/year. Overall, this represents a slight improvement in the amenity of the wind environment in the surrounding area.

#### Overall Assessment of Design

5 Taken overall, the original development design causes a relatively small change in wind conditions in the pedestrian areas surrounding the site. This is partly attributed to beneficial aspects of the massing distribution in the design, which includes setbacks and stepped facades on the eastern and western ends of the building.

#### Effects of Design Changes

6 Additional testing of design changes showed that wind conditions where speeds were increased above the District Plan Safety Criteria by the development could be somewhat improved. Of the options tested, (a) additional trees and planting and (b) a canopy on the edge of the building undercroft, performed better.

#### Other Design Considerations

7 The decision was made to include the NZ Ballet building as part of the existing situation. While this building is considered a "temporary" building, it has been in place since 2018, and there is no defined date for its removal. Accordingly, the existing wind conditions are those determined, in part, by this building. It is expected that comparing the proposed development with the previously "vacant" carpark would result in relatively small changes in effects.

8 The existing pedestrian overbridge across Wakefield was included in the wind tunnel testing. This has been removed from the design. The effects of this removal are likely to be a slight overall improvement in wind conditions in the immediate area.

## 9 LIMITATIONS

This report ('Report') has been prepared by WSP exclusively for Willis Bond Capital Partners No 3 Limited ('Client') in relation to the pedestrian level wind study of the proposed development for the Michael Fowler Centre carpark in Wellington ('Purpose') and in accordance with our offer of service dated 26<sup>th</sup> July 2021. The findings in this Report are based on and are subject to the assumptions specified in the Report. WSP accepts no liability whatsoever for any reliance on or use of this Report, in whole or in part, for any use or purpose other than the Purpose or any use or reliance on the Report by any third party.

## APPENDIX A WIND EFFECTS ON PEOPLE

### GENERAL

One of the primary parameters in any assessment of how wind affects people are the peak gust speeds and the associated rates of change of the wind speed. Table A1 below gives a summary of the typical effects of 3-second gust speeds on people in an urban situation (after Penwarden).

Table A1:

Typical effects of a 3-second gust on pedestrians.

Wind Description	Gust Speed (m/s)	Effects
Moderate breeze	5 - 8	Raises dust, dry soil and loose paper; hair disarranged.
Fresh breeze	8 - 11	Force of wind felt on body; limit of agreeable wind.
Strong breeze	11 - 14	Walking irregular; hair blown straight; umbrellas used with difficulty.
Near gale	14 - 17	Walking difficult to control; wind noise unpleasant; body leans into wind.
Cale	17 - 21	Great difficulty with balance; body blown sideways; dangerous for elderly people.
Strong gale	21 - 24	People blown over by gusts.
Storm	24 - 28	Impossible to stand up; necessary to crouch and hold onto a support.
Violent Storm	>28	Unlikely to be ever experienced.

The wind performance of an urban area may be classified in a number of different ways, but one of the simplest and most widely accepted is in terms of the "annual maximum 3 second gust". The criteria used (after Melbourne) have been established internationally for some time and are given in the Table A2. A location which experiences a maximum annual gust speed within a certain category in Table A2 will typically also experience a range of wind conditions throughout the year, which result in the criteria being appropriate.

The expression "annual maximum 3 second gust" is shorthand for a description of the probability of occurrence of a certain level of wind speed, given that both weather conditions and wind turbulence vary in an unpredictable manner. It should be noted that the expression describes a wind speed which is in fact a little less than the highest wind speed that one would be likely to record if an anemometer were mounted in a city street for a year.

Table A2:

#### Pedestrian level gust speed criteria.

Category	Annual Maximum 3 Second Gust (m/s)	
А	23 and above	Dangerous. Completely unacceptable in a main public area.
В	16 to 23	Undesirable in a main public area.
С	Less than 16	Generally acceptable for walking.
D	Less than 13	Generally acceptable for stationary short exposure activities (e.g. window shopping, standing or sitting in plazas).
E	Less than 10	Generally acceptable for stationary long exposure activities (e.g. outdoor restaurants).

#### WELLINGTON

For Wellington wind tunnel studies, we calculate a gust speed, which is based on the annual maximum hourly mean speed for a particular wind direction. It describes the wind conditions which are equalled or exceeded during 6 hours per year, within a 20° sector centred on a particular wind direction. The gust speed is calculated using the mean wind speed and the corresponding standard deviation of the wind speed multiplied by a factor, as defined in the Wellington City District Plan.

The Wellington City District Plan specifies a gust speed of 20m/s as a maximum safety limit. However, existing wind conditions exceed this limit in many parts of the city. The criteria therefore describes a desired wind environment, which may not always be achievable in practice.

We suggest the use of the descriptive terms in Table A3 as a means of interpretation of how the wind speeds measured in a wind tunnel study compare with the speeds which typically occur at other locations in Wellington City. It may be seen that the gust speed of 20m/s, which is the maximum allowable by the Wellington City Council, is only in the moderately high category using these descriptions. Note that this table simply compares the level of wind speeds that occur from place to place within Wellington, whereas Table A1 describes the effects of these wind speeds on people.

Note the differences between the three tables listed here, as they use similar wind speed measurements, but describe different issues:

Table A1:	Describes the effects on people when they experience a gust of wind.
Table A2:	Internationally recognised criteria for determining the acceptability of wind
	conditions at a certain location throughout the year.
Table A3:	Relative descriptions of the variation of wind conditions that occur at different
	locations in Wellington.

Table A3:Suggested descriptive terms for the range of gust wind speeds which typically<br/>occur at different locations within Wellington City.

Annual maximum gust speed (m/s)	
11 and below	very low
12 – 14	low
15 – 17	moderate
18 – 20	moderately high
21 - 23	high
24 – 26	very high
27 and above	extremely high

## APPENDIX B DISTRICT PLAN WIND RULES

Relevant sections of the Wellington City District Plan, including the Objectives, Policies and Standards relating to wind the wind effects of buildings are reproduced below. These can be found on the Wellington City Council website (<u>http://wellington.govt.nz/your-council/plans-policies-and-bylaws/district-plan/eplan</u>).

### OBJECTIVES

#### **OBJECTIVE - EFFECTS OF NEW BUILDING WORKS**

12.2.5 Encourage the development of new buildings within the Central Area provided that any potential adverse effects can be avoided, remedied or mitigated.

#### POLICIES

To achieve this objective, Council will:

- 12.2.5.6 Ensure that buildings are designed to avoid, remedy or mitigate the wind problems that they create and where existing wind conditions are dangerous, ensure new development improves the wind environment as far as reasonably practical.
- 12.2.5.7 Ensure that the cumulative effect of new buildings or building alterations does not progressively degrade the pedestrian wind environment.
- 12.2.5.8 Ensure that the wind comfort levels of important public spaces are maintained.
- 12.2.5.9 Encourage consideration of wind mitigation measures during the early stages of building design and ensure that such measures are contained within the development site.

#### STANDARDS

#### 13.6 Central Area Standards

#### 13.6.3.5 Wind

- 13.6.3.5.1 The following wind standards apply to the Central Area, excluding buildings and structures for Operational Port Activities in the Operational Port Area.
- 13.6.3.5.2 New buildings, structures, or additions above 18.6 metres in height will be designed to comply with the following standards:

(a) SAFETY: The safety criteria shall apply to all public space. The maximum gust speed shall not exceed 20 m/s. If the speed exceeds 20 m/s with the proposed development, it must be reduced to 20 m/s or below.

(b) CUMULATIVE EFFECT: The cumulative criteria shall apply to all public space. Any proposed development must meet the requirements for both of the following wind strengths, at each measurement location.

Wind strength	Change in annual days of occurrence with the development at all measurement points	Requirements on developer
Strong (mean hourly wind speed = 3.5 m/s)	If days that 3.5 m/s is equalled or exceeded increase by more than 20 days/year (i.e. 5.5% of the year)	Reduce change in days to a maximum of 20 days.
Moderate (mean hourly wind speed = 2.5 m/s)	If days that 2.5m/s is equalled or exceeded increase by more than 20 days/year (i.e. 5.5% of the year)	Reduce change in days to a maximum of 20 days.

(c) Under the Cumulative Effect Criterion, the overall impact of a building on the wind conditions must be neutral or beneficial.

(d) COMFORT: The comfort criteria only applies to the public spaces listed in standard 13.6.3.4

Comfort wind strength	Annual days of occurrence with the development	Requirements on developer
Mean hourly wind speed = 2.5 m/s	If days that 2.5 m/s is equalled or exceeded increase above 73 days/year (i.e. 20% of the year).	If existing building exceeds 73 days, then reduce number of days for proposed building to existing levels. If existing building is below 73 days then reduce number of days for proposed building to below 73 days.

13.6.3.5.3 To show that a development complies with these standards a wind report must be supplied that meet the requirements outlined in Appendix 8 (see also section 3.2.2.15 of the Information Requirements).

For information purposes, the effects of wind speeds, which correspond to those used in, the safety criteria, are

20 metres/second gust - Completely unacceptable for walking.

the comfort or cumulative criteria, are

3.5 metres/second mean - Corresponds to threshold of danger level. 2.5 metres/second mean - Generally the limit for comfort when sitting for lengthy periods in an open space.

## APPENDIX C WELLINGTON WIND CLIMATE

The wind over Wellington City is predominantly either northerly or southerly. This is demonstrated by a sample wind rose, plotted in Figure C1, for the wind at a height of 150 m. The rose is obtained from the wind data listed in Figure C2.

The wind data is derived from that recorded over a 47-year period at Wellington Airport. The mean wind speed at 150 m over the city is calculated to be the same as that at the airport reference anemometer at a height of 10 m, but with the northerly winds rotated 10 degrees to the west. This relationship is based on work carried out by Jackson (1976). It is also consistent with the Deaves and Harris (1978) wind model.

From this data, the following values have been estimated for the mean hourly wind speeds that occur during 6 hours per year for a 20° sector, centred on the listed wind direction.

#### Reference Wind Speeds for Wellington City

Direction (degrees)	150	170	190	210	320	340	360	020
Speed (m/s)	15	20	22	22	19	22	20	15

The measured wind speeds around a building, as quoted in this report, are calculated gust speeds based on the mean wind speed that is exceeded for only 6 hours per year and the corresponding standard deviation in the wind speed.

## APPENDIX D WIND TUNNEL BOUNDARY LAYER

The WSP Research and Innovation Centre wind tunnel is a recirculating type, with an overall length of approximately 30 m. The working section measures 3.0 m wide x 1.5 m high. The airflow is generated by a six blade, 2.0 m diameter, 45 kW axial flow fan in the upper circular section of the wind tunnel. The maximum air speed in the working section is around 15m/s. A variable speed drive controls the air speed. Figure D1 shows a view of the wind tunnel.

The section of the wind tunnel upwind of the turntable allows the development of a deep turbulent boundary layer to simulate the natural atmospheric boundary layer at an appropriate scale. The correct velocity and turbulence profiles are generated by vertical spires, horizontal fence elements and an array of wooden blocks on the floor of the tunnel.

The Deaves and Harris (1978) mathematical model of the structure of strong winds is recognised as the recommended model for engineering design purposes. It is used in the wind loading design Standard, AS/NZS 1170.2. The four main terrain categories defined in AS/NZS 1170.2 are:

#### **Terrain Categories**

- 1 Flat, treeless plains, sea coasts
- 2 Open terrain, well scattered obstructions (air fields)
- 3 Suburban, industrial and well wooded areas
- 4 City centre condition

## APPENDIX E FLOW VISUALISATION

### METHODOLOGY

Flow visualisation using bran flakes provides a means of quickly identifying the relative wind speeds over the surface of a model.

The bran flakes are sieved to provide flakes between 1.0 mm and 1.4 mm in size. With the wind tunnel switched off, the model is sprinkled with a thin uniform layer of the bran. The layer is approximately two bran flakes deep, but it completely obscures the surface of the model. The wind tunnel speed is then steadily increased over a period of 20 minutes and the bran is progressively blown away. The areas where the bran first blows away indicate where the highest gust speeds are likely to occur. In other areas the bran accumulates slowly and these are generally where the lowest gust speeds occur. The changing patterns in the bran are photographed as the test proceeds.

The photographs from each test are processed to give the contour images shown in the wind report. Areas of the photographs that change from one photograph to the next in the test sequence are coloured, to give contours of increasing erosion. These contours correspond loosely to gust wind speeds on the surface of the model, although no accurate gust speed can be determined for a particular location from the contours. It is possible to compare the results from two separate tests, but the comparison must be made with caution because each test is inevitably slightly different. Ideally, the bran tests should only be used as a rough visual indication of where the highest wind speeds occur and as a guide to where hot wire speed measurements should be concentrated.

While the test is in progress, the movement of the bran is also useful for visualisation of the flow around the model. Usually this only indicates the direction of the flow at ground level, but in certain flow conditions (e.g. in vortices or in high turbulence) the bran flakes also become airborne and the three-dimensional flow is then apparent. Unfortunately, this movement is not detectable in the still photographs.

Windiness	Elapsed Time	Fan Control Frequency	Photograph	Reference Tunnel Speed	
	(minutes)	(Hz)		(m/s)	
	0	0	0	0.0	
10	2	7	1	2.2	
9	4	10	2	3.1	
8	6	13	3	4.0	
7	8	16	4	4.9	
6	10	18	5	5.8	
5	12	21	6	6.7	
4	14	25	7	7.8	
3	16	28	8	9.0	
2	18	32	9	10.1	
1	20	35	10	11.2	

The details of the test procedure are as follows:

The tunnel speed is held constant at each control setting for two minutes before taking each photograph. This provides a reasonable time for the bran erosion to stabilise after each speed increase.

Although the local gust speed is the greatest single factor in producing movement of the bran flakes, there are numerous other factors that make it difficult to produce an accurate correlation with the measured wind speeds. These include:

The model surface:	The bran can accumulate on rough or sticky surfaces and in cracks and hollows.
Loose bran flakes:	The bran moves more easily when it is loose, e.g. at the edge of a cleared area, than when it is closely packed. Therefore, a clearing may expand rapidly once it has been initiated.
Discontinuities:	The bran tends to be disturbed around corners and small obstructions in the airflow. It is not easily disturbed in regions of flat, uniform flow.
Vertical wind flow:	The bran is more easily disturbed where there is a downward component in the air velocity than where the flow is horizontal.
Turbulence:	The bran tends to be disturbed by turbulence and fluctuating flow direction.
Tunnel gusts:	Occasional random low frequency fluctuations in the tunnel speed produce rapid changes in the bran erosion patterns. These tunnel gusts occur about once or twice per minute.
Vortices:	Bran flakes can accumulate in the core of a steady local vortex. This then appears to be a comparatively calm area in the photographs because the vortex is not visible.
Bran mounds:	The bran can accumulate in mounds as each test proceeds, and the mounds subsequently modify the flow conditions in their vicinity.

### CALIBRATION

Figure E2 shows a bran erosion contour image for the calibration building specified in Appendix 7 of the Wellington City District Plan. The calibration building is an isolated rectangular block, measuring 60m high, and 15m square in plan, at full-scale. This building was built at a scale of 1:264, which is the scale of the WSP Research and Innovation Centre wind tunnel model of Wellington City. The building was tested in the standard terrain category 3 atmospheric boundary layer simulation, which is used for environmental building studies in Wellington City. Figure E1 shows the grid on the wind tunnel floor that was used to determine the extent of the erosion. The circle marked in Figure E1 indicates an area 50m in diameter (at full-scale) which is centred on the back face of the model, as specified in the Wellington City District Plan. Contour number 7 (i.e. windiness="7") corresponds to approximately 80% of this circle being cleared of bran.

## APPENDIX F GUST WIND SPEEDS

A change of 1 m/s in the wind speeds is not considered significant within the limitations of the test method, whereas a change of 2 m/s generally indicates a reproducible wind effect.
